

Rule System

Can I route downloads from specific sites to different folders?

Yes, you put forward slashes between the naming masks, for example your naming mask would look like so:

date*/*host*/*name*.ext

So that would come out with the files placed into a folder for the current date, then a folder for the host site, then the filename and it's extention.

I find that's useful to keep new photos seperated from the older ones. But you may prefer to put the date inside the website folder or not include it at all, totally up to you.

I've found downloading from different places the results using *host* isn;t always consistant, so if that doesn't give you your desired result you can also try

page_title or ***refer*** instead.

Although I've not found either of those to be 100% reliable either. Failing all of those, you can just add the site name in manually during download

like so **google.com/*host*/*name*.ext***

Hope that helps :)

I've worked out a lot of useful little tricks in this program that I've had to figure out for myself, so I might put a blog post together [on my site](#) at some point soon, as this FAQ is awful and the top questions don't even read well, so think I need to do somethign about it lol.
